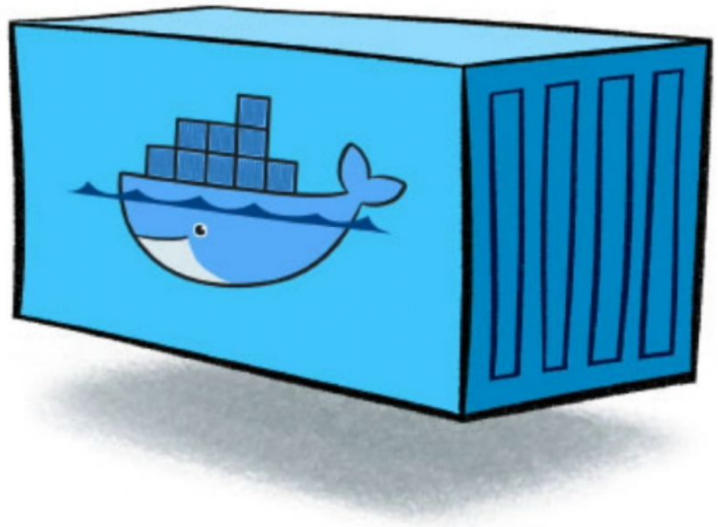
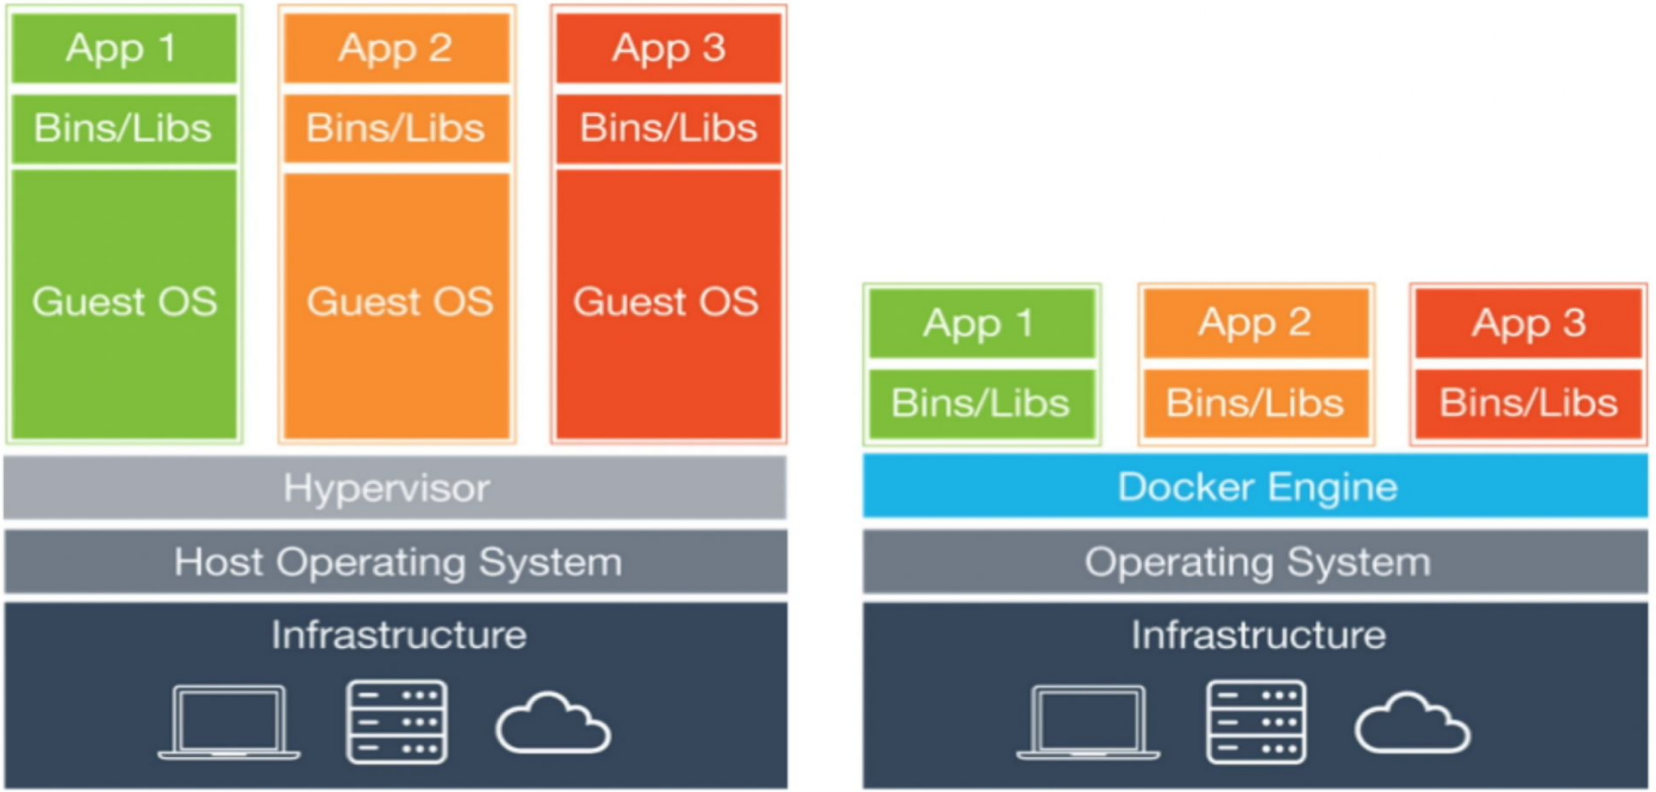
Docker Benefits

- Isolation
- App + Dependencies
- Run anywhere



Virtual Machines vs. Containers

Virtual Machine vs. Containers



Virtual Machines vs. Containers

- **Virtual Machines**
- Huge in size(in GB)
- Have a Kernel
- Have unwanted Libs, Bins,and Utils
- More CPU & Memory
- More time to boot up

- **Containers**
- Small in size(in MB)
- Have no Kernel
- Have bare-minimal Libs, Bins and Utils
- Light weight & fast
- Less CPU & Memory

```
Docker Container Basics:
========================

docker pull <image name>
docker pull nginx

docker run -d -p 80:80 nginx

docker run -it -p 80:80 nginx

docker container logs <id>

docker exec <container name or id > <command to
docker exec afbg ls

docker exec -it <container id> /bin/bash

docker container stop  <id>

docker container start  <id>
```

Today we will learn :

1. What are images
2. How to pull image
3. How to run a container using an image
4. Basic Commands

TIPS & TRICKS

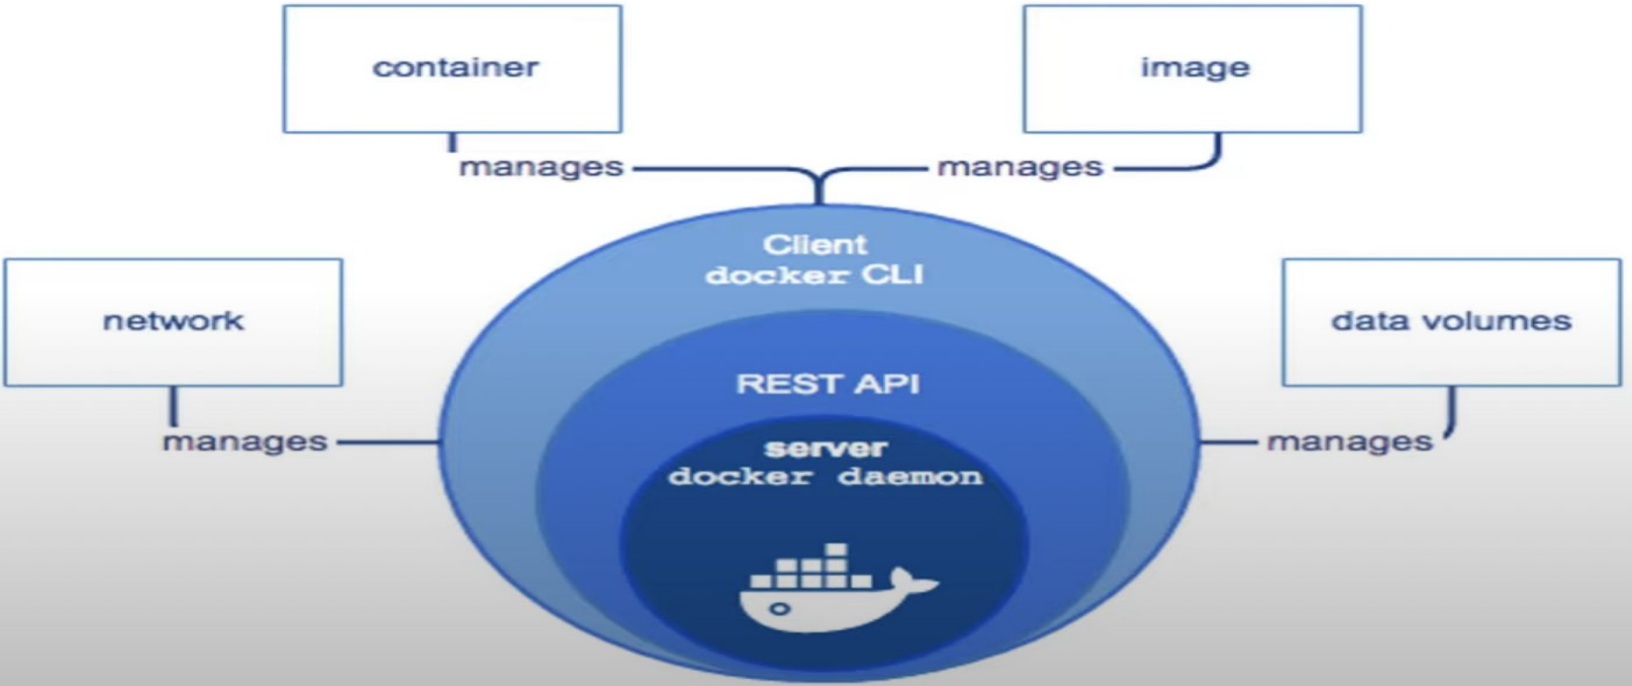
What are Images

Docker Images are templates used to create Docker containers
Container is a running instance of image

Where are Images Stored

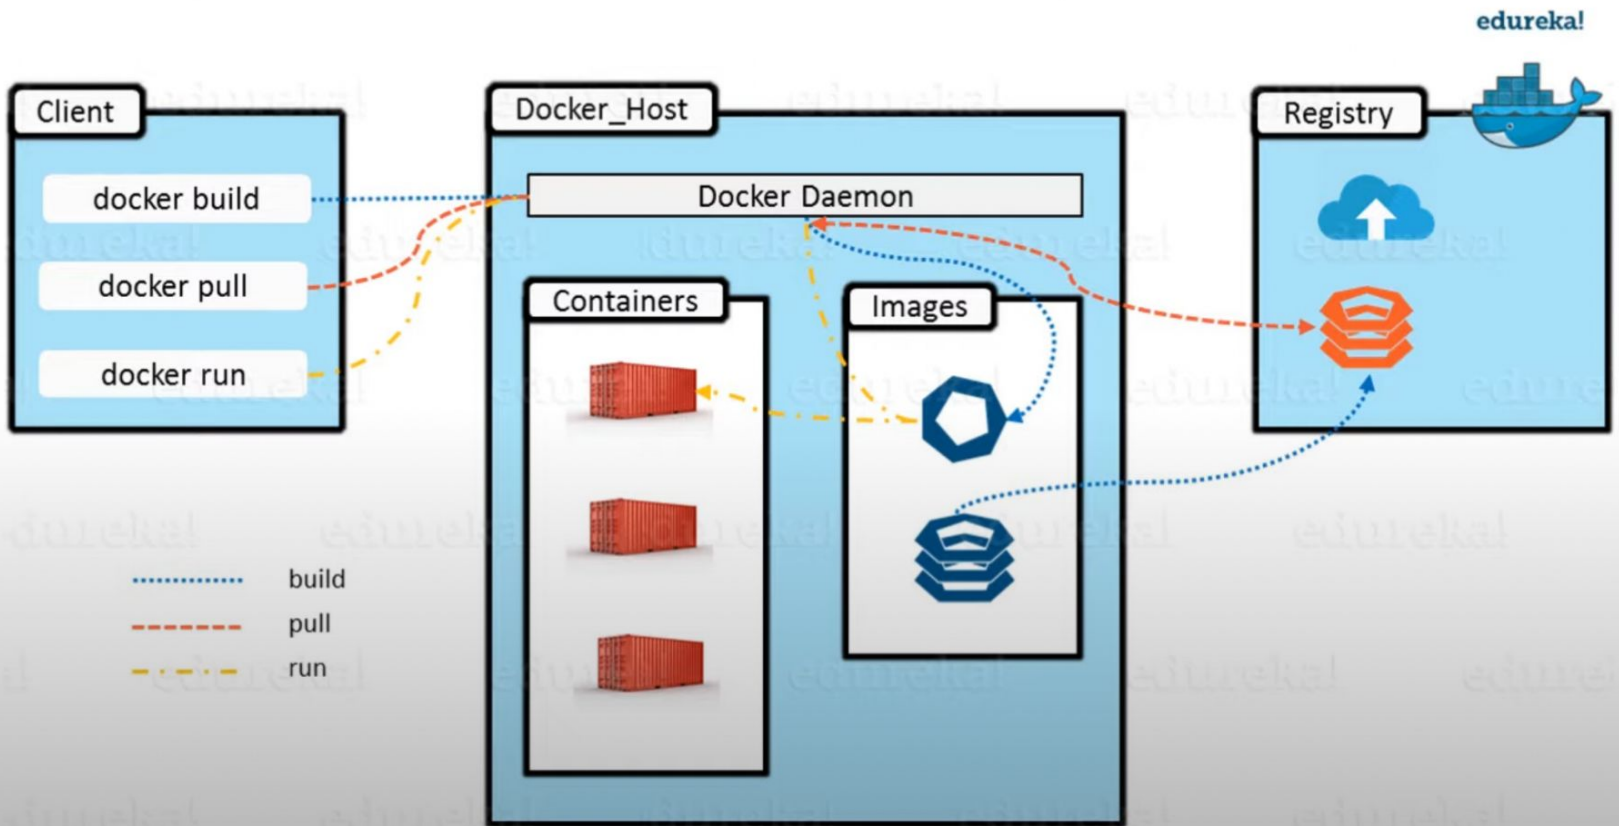
Registries (e.g. docker hub)

Docker Engine



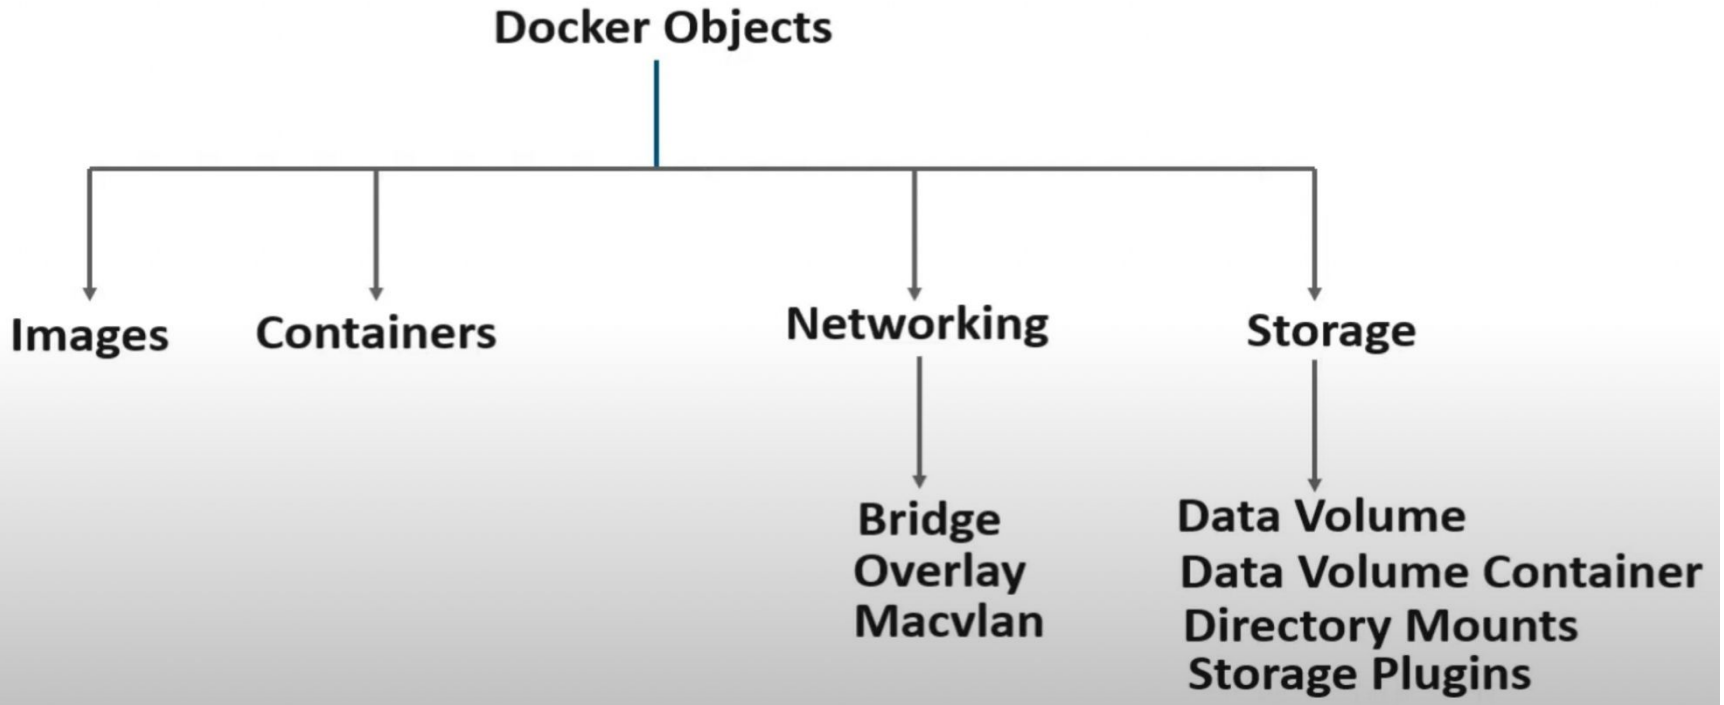
1. Docker daemon which is used for the application interact with docker daemon
2. Docker cli is command line interface which is used for interacting with docker daemon
3. Docker client talk with docker daemon building ,distributing of docker containers
4. Client and daemon can run on the same system
5.

Docker Architecture



1. Docker client can communicate with more than one daemon
2. Docker Host provide complete execute host
3. It contain network and storage,images
4. Daemon responsible for all container related actions
5. Docker daemon is pull and build image as requested by client

Docker Components



Docker Registry

Docker Registry

> This page contains information about hosting your own registry using the open source Docker Registry. For information about Docker Hub, which offers a hosted registry with additional features such as teams, organizations, web hooks, automated builds, etc, see Docker Hub.

What it is

The Registry is a stateless, highly scalable server side application that stores and lets you distribute Docker images. The Registry is open-source, under the permissive Apache license.

You can find the source code on GitHub.

Why use it

You should use the Registry if you want to:

- tightly control where your images are being stored
- fully own your images distribution pipeline
- integrate image storage and distribution tightly into your in-house development workflow

- Containers are created they should be able to communicate with each other
-

Docker Images
BEGINNERS

1. What are images
2. How to pull image
3. How to run a container using an image
4. Basic Commands

TIPS & TRICKS

What are Images
Docker Images are templates used to create Docker containers
Container is a running instance of image

Where are Images Stored
Registries (e.g. docker hub)

1. File which contain what all things will be required to create container
2. Container is a running instance of the image
3. Images are stored in the docker hub
4. https://github.com/docker/compose

Docker Compose

Compose is a tool for defining and running multi-container Docker applications. With Compose, you use a Compose file to configure your application's services. Then, using a single command, you create and start all the services from your configuration. To learn more about all the features of Compose see the list of features.

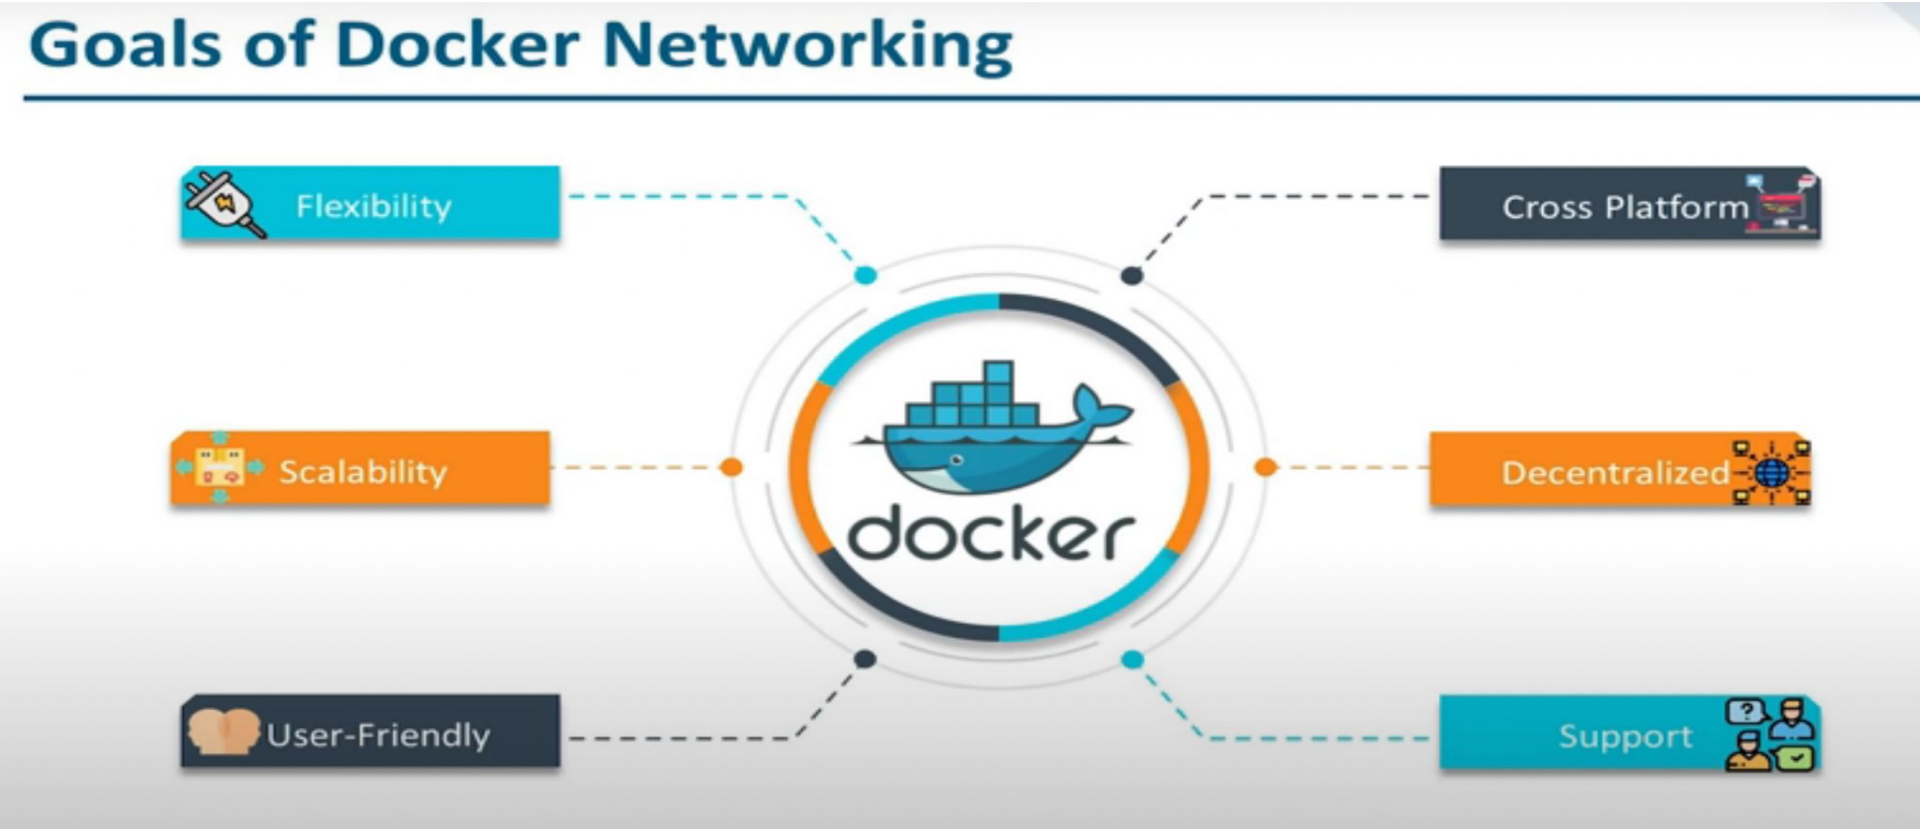
Compose is great for development, testing, and staging environments, as well as CI workflows. You can learn more about each case in Common Use Cases.

Using Compose is basically a three-step process.

1. Define your app's environment with a `Dockerfile` so it can be reproduced anywhere.
2. Define the services that make up your app in `docker-compose.yml` so they can be run together in an isolated environment.
3. Lastly, run `docker-compose up` and Compose will start and run your entire app.

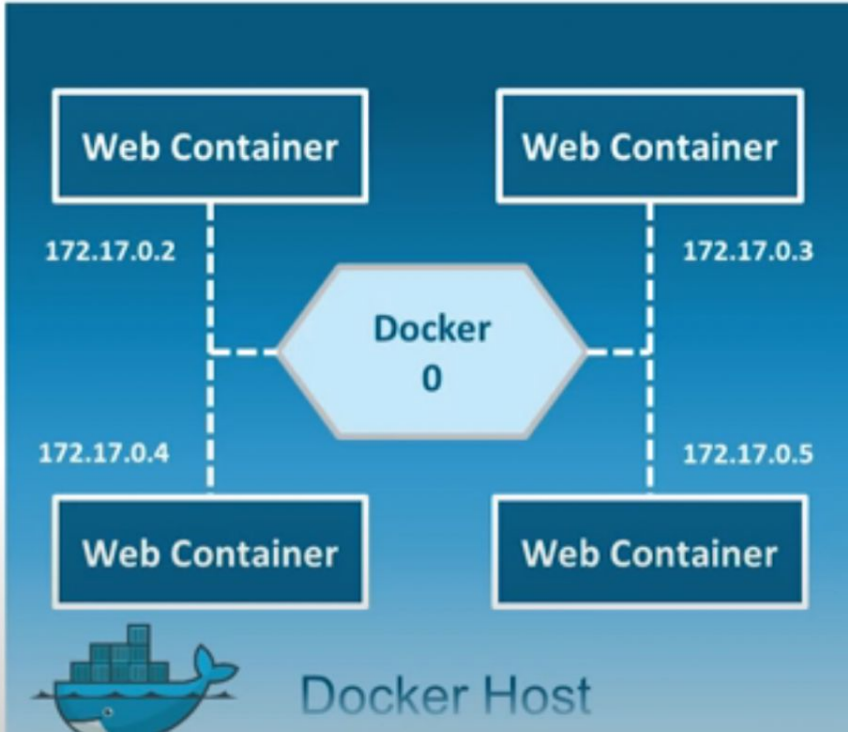
Docker Compose

Docker Networking



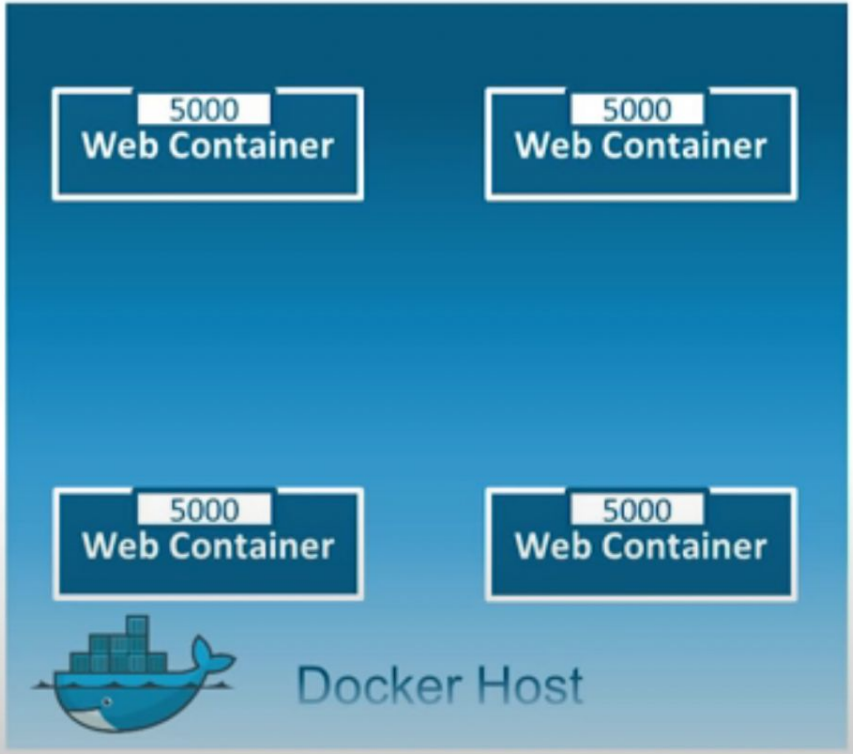
Network Drivers: Bridge

The default network driver. If you don't specify a driver, this is the type of network you are creating. Bridge networks are usually used when your applications run in standalone containers that need to communicate.

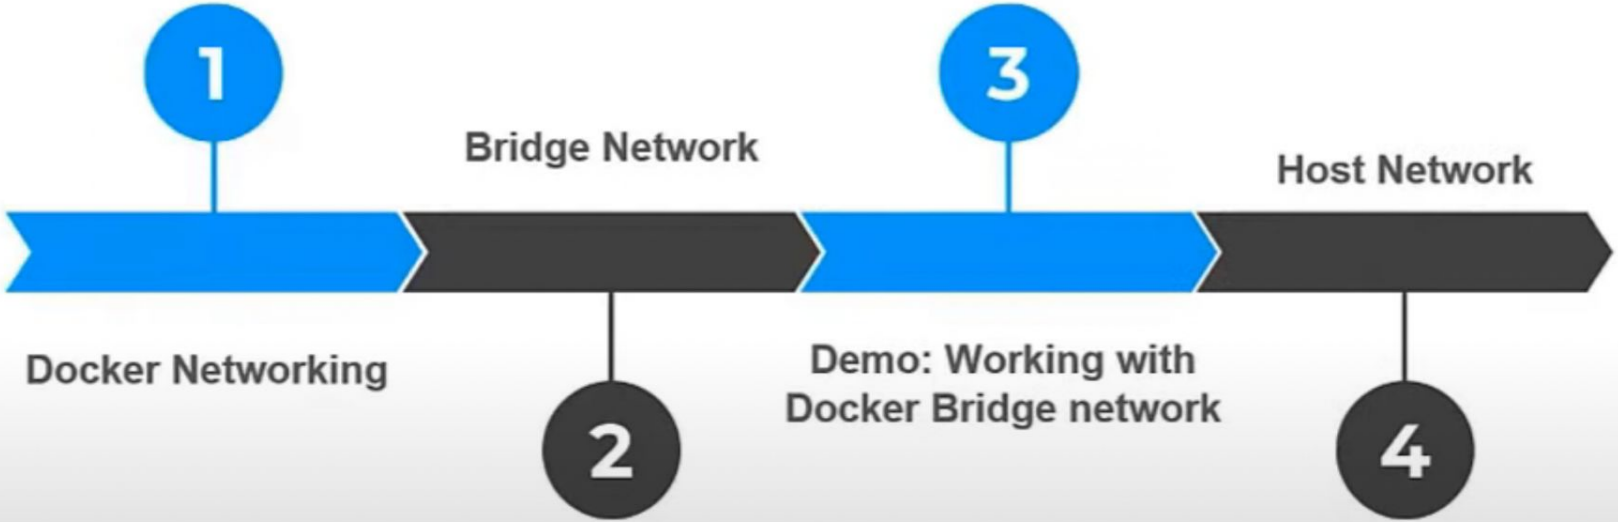


Network Drivers: Host

For standalone containers, removes network isolation between the container and the Docker host, and uses the host's networking directly.



Agenda



1
Docker Networking
2
Bridge Network
3
Demo: Working with
Docker Bridge network
4
Host Network

Agenda

Demo: Working with Docker Network Commands
8

```
sharathhanswadi@Chandras-MacBook-Pro getting-started % docker info
Client:
 Context:    default
 Debug Mode: false
 Plugins:
  buildx: Docker Buildx (Docker Inc., v0.8.2)
  compose: Docker Compose (Docker Inc., v2.5.0)
  sbom: View the packaged-based Software Bill Of Materials (SBOM) for an image (Anchore Inc., 0.6.0)
  scan: Docker Scan (Docker Inc., v0.17.0)

Server:
 Containers: 5
  Running: 3
  Paused: 0
  Stopped: 2
 Images: 10
 Server Version: 20.10.14
 Storage Driver: overlay2
  Backing Filesystem: extfs
  Supports d_type: true
  Native Overlay Diff: true
  userxattr: false
 Logging Driver: json-file
 Cgroup Driver: cgroupfs
 Cgroup Version: 2
```

```
docker network ls
NETWORK ID     NAME       DRIVER    SCOPE
d9d67d745590   bridge     bridge    local
ec714e10e880   host       host      local
5ebf2db21d7d   minikube   bridge    local
b05bdc4ca458   none       null      local
```

1) Bridge

2) Host

3) Null

4) Macvlan

5) Overlay

1. Bridge will be always default network
2. Bridge is used when multiple docker containers are running on the same host machine
3.

What is Docker Networking?

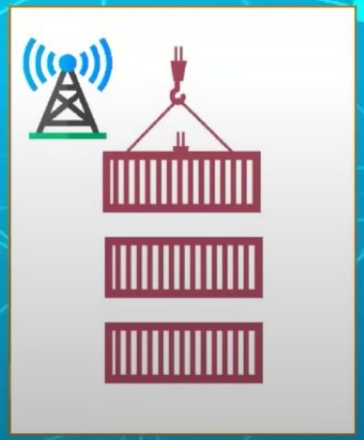
Docker networking enables a user to link a Docker container to as many networks as he/she requires

What is Docker Networking?

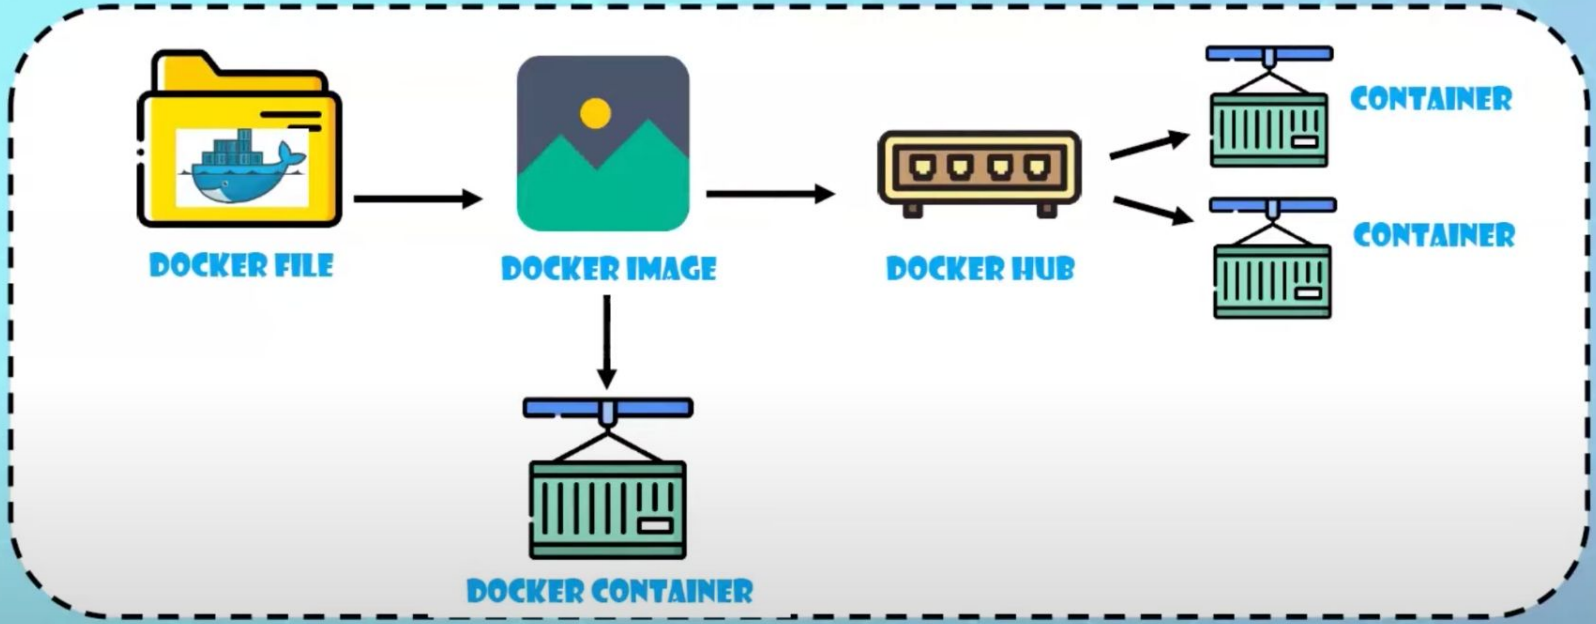
Docker networking enables a user to link a Docker container to as many networks as he/she requires

Docker Networks are used to provide complete isolation for Docker containers

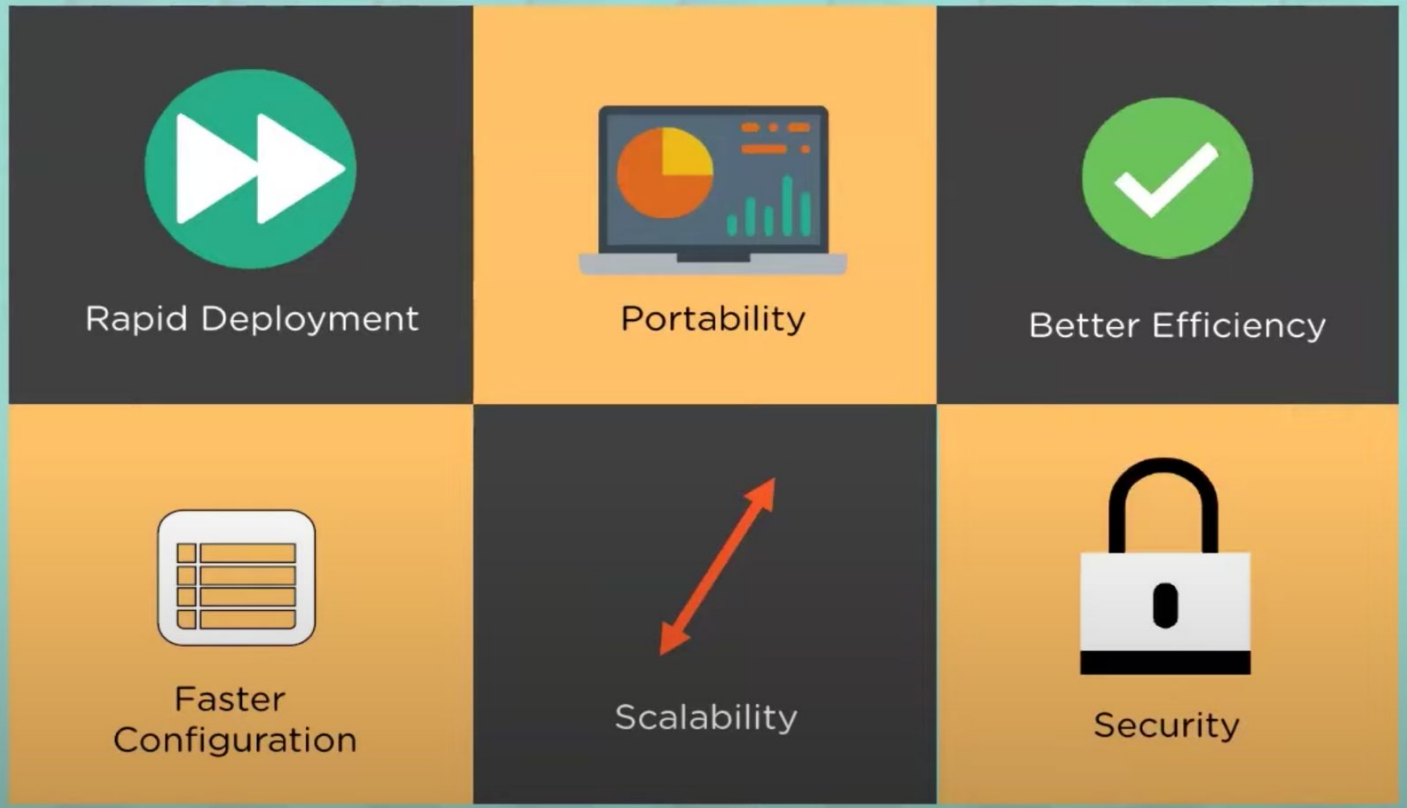
Note: A user can add containers to more than one network



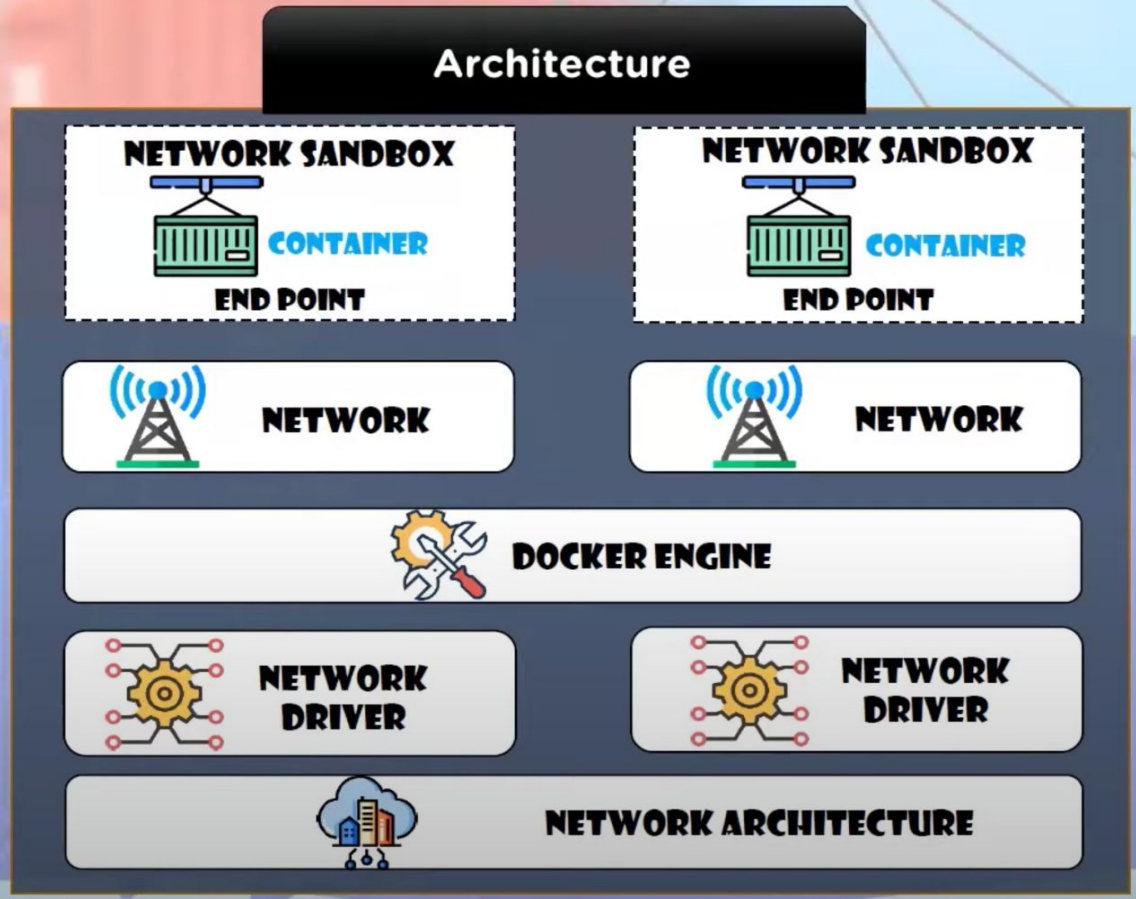
How Docker Networking Works?



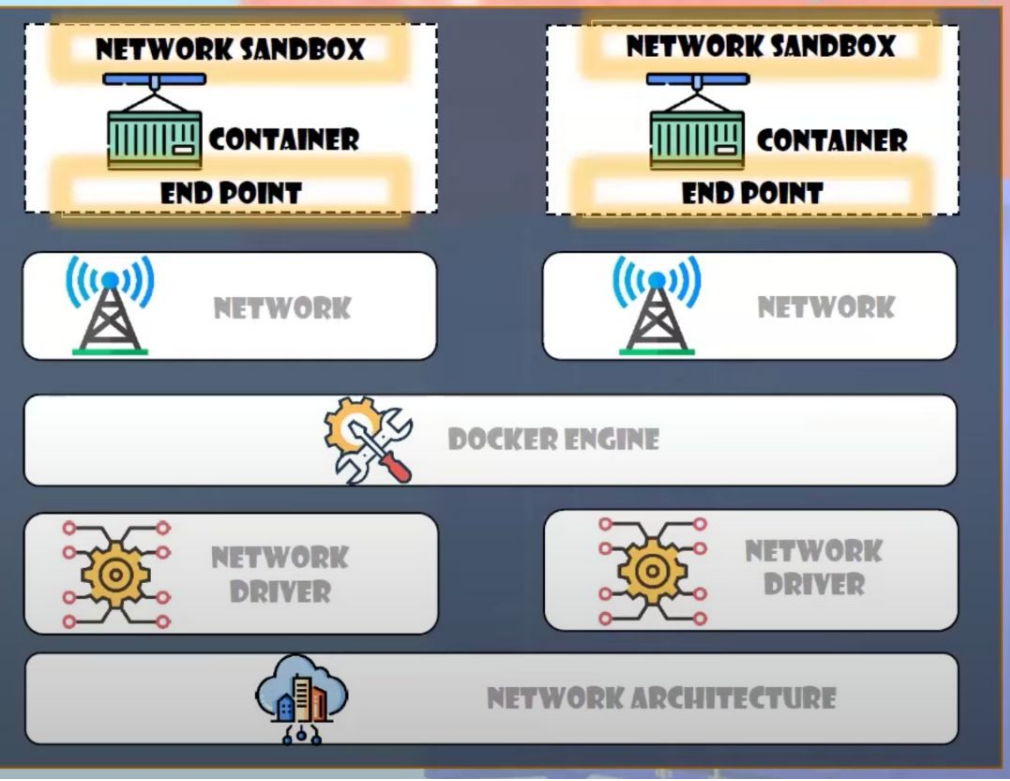
Advantages of Docker Networking



Container Network Model



Container Network Model



- It is an isolated sandbox that holds the network configuration of containers
- Sandbox is created when a user requests to generate an endpoint on the network
- It can have several endpoints in a network, as it represents a container's network configuration such as IP-address, MAC-address, DNS etc.
- End point establishes the connectivity for container services (within a network) with other services

Network Drivers

The network drivers used in Docker are below:

BRIDGE

HOST

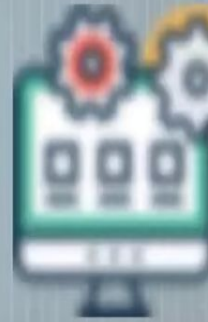
NONE

OVERLAY

MACVLAN

BRIDGE

- It is a private default network created on the host
- Containers linked to this network have an internal IP address through which they communicate with each other easily
- The Docker server (daemon) creates virtual ethernet bridge docker0 that performs the operation by automatically delivering packets among various network interfaces



MACVLAN

BRIDGE

HOST

- It is a public network
- It utilizes the host's IP address and TCP port space in order to display the services running inside the container

Network Drivers

- In this network driver, the Docker containers will neither have any access to external networks nor will it be able to communicate with other containers

NONE

OVERLAY

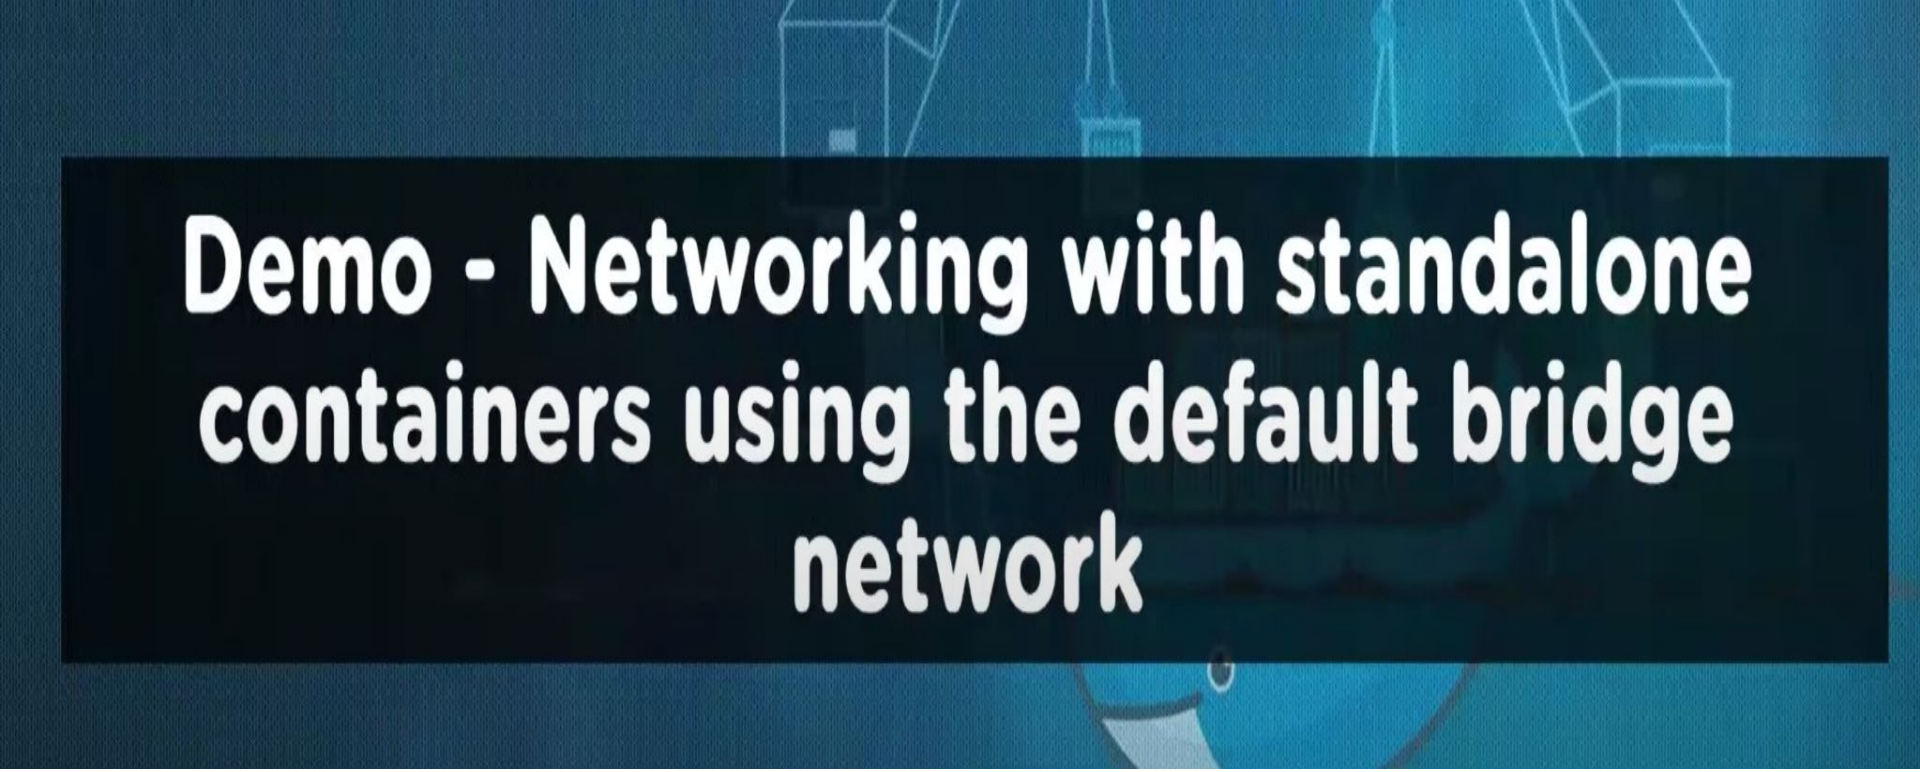
MACVLAN

Network Drivers

- This is utilized for creating an internal private network to the Docker nodes in the Docker swarm cluster

BRID

OVERLAY



Demo - Networking with standalone containers using the default bridge network
